Scale-free networks are a type of network characterized by the presence of large hubs. A scale-free network is one with a power-law degree distribution. Networks with power-law distributions are called scale-free because power laws have the same functional form at all scales.

One quick way to understand why power laws are called "scale-free" or "scale-invariant" is to compare a distribution $P(x)$ at $x = x_0$ and $x = \lambda x_0$. Thus, the exponential distribution is not said to be scale-free. What is the difference between graph-partitioning and graph.

There are obviously scientific reasons for it. In contrast, we find that social networks are at best weakly scale free, and although a power-law distribution can be a statistically plausible model for these networks, it is often not a better model than a non-scale-free distribution.
